## LECTURE 5

### **Sorting Lower Bounds**

- Decision trees

### **Linear-Time Sorting**

- Counting sort
- Radix sort

### **Appendix: Punched cards**

# How fast can we sort?

All the sorting algorithms we have seen so far are *comparison sorts*: only use comparisons to determine the relative order of elements.

- *E.g.*, insertion sort, merge sort, quicksort, heapsort.

The best worst-case running time that we've seen for comparison sorting is  $O(n \lg n)$ .

*Is  $O(n \lg n)$  the best we can do?*

*Decision trees* can help us answer this question.

# Decision-tree example

Sort  $\langle a_1, a_2, \dots, a_n \rangle$

Each internal node is labeled  $i:j$  for  $i, j \in \{1, 2, \dots, n\}$ .

- The left subtree shows subsequent comparisons if  $a_i \leq a_j$ .
- The right subtree shows subsequent comparisons if  $a_i > a_j$ .

# Decision-tree example

Sort  $\langle a_1, a_2, a_3 \rangle$   
 $= \langle 9, 4, 6 \rangle$ :

Each internal node is labeled  $i:j$  for  $i, j \in \{1, 2, \dots, n\}$ .

- The left subtree shows subsequent comparisons if  $a_i \leq a_j$ .
- The right subtree shows subsequent comparisons if  $a_i > a_j$ .

# Decision-tree example

Sort  $\langle a_1, a_2, a_3 \rangle$   
 $= \langle 9, 4, 6 \rangle$ :

Each internal node is labeled  $i:j$  for  $i, j \in \{1, 2, \dots, n\}$ .

- The left subtree shows subsequent comparisons if  $a_i \leq a_j$ .
- The right subtree shows subsequent comparisons if  $a_i > a_j$ .

# Decision-tree example

Sort  $\langle a_1, a_2, a_3 \rangle$   
 $= \langle 9, 4, 6 \rangle$ :

Each internal node is labeled  $i:j$  for  $i, j \in \{1, 2, \dots, n\}$ .

- The left subtree shows subsequent comparisons if  $a_i \leq a_j$ .
- The right subtree shows subsequent comparisons if  $a_i > a_j$ .

# Decision-tree example

Sort  $\langle a_1, a_2, a_3 \rangle$   
 $= \langle 9, 4, 6 \rangle$ :

Each leaf contains a permutation  $\langle \pi(1), \pi(2), \dots, \pi(n) \rangle$  to indicate that the ordering  $a_{\pi(1)} \leq a_{\pi(2)} \leq \dots \leq a_{\pi(n)}$  has been established.

# Decision-tree model

*A decision tree can model the execution of any comparison sort:*

- One tree for each input size  $n$ .
- View the algorithm as splitting whenever it compares two elements.
- The tree contains the comparisons along all possible instruction traces.
- The running time of the algorithm = the length of the path taken.
- Worst-case running time = height of tree.

# Lower bound for decision-tree sorting

**Theorem.** Any decision tree that can sort  $n$  elements must have height  $\Omega(n \lg n)$ .

*Proof.* The tree must contain  $\geq n!$  leaves, since there are  $n!$  possible permutations. A height- $h$  binary tree has  $\leq 2^h$  leaves. Thus,  $n! \leq 2^h$ .

$$\begin{aligned} \therefore h &\geq \lg(n!) && (\lg \text{ is mono. increasing}) \\ &\geq \lg((n/e)^n) && (\text{Stirling's formula}) \\ &= n \lg n - n \lg e \\ &= \Omega(n \lg n). \quad \square \end{aligned}$$

# Lower bound for comparison sorting

**Corollary.** Heapsort and merge sort are asymptotically optimal comparison sorting algorithms. 

# Sorting in linear time

**Counting sort:** No comparisons between elements.

- **Input:**  $A[1 \dots n]$ , where  $A[j] \in \{1, 2, \dots, k\}$ .
- **Output:**  $B[1 \dots n]$ , sorted.
- **Auxiliary storage:**  $C[1 \dots k]$ .

# Counting sort

```
for  $i \leftarrow 1$  to  $k$   
    do  $C[i] \leftarrow 0$   
for  $j \leftarrow 1$  to  $n$   
    do  $C[A[j]] \leftarrow C[A[j]] + 1$  ▷  $C[i] = |\{\text{key} = i\}|$   
for  $i \leftarrow 2$  to  $k$   
    do  $C[i] \leftarrow C[i] + C[i-1]$  ▷  $C[i] = |\{\text{key} \leq i\}|$   
for  $j \leftarrow n$  downto  $1$   
    do  $B[C[A[j]]] \leftarrow A[j]$   
         $C[A[j]] \leftarrow C[A[j]] - 1$ 
```

# Running time

If  $k = O(n)$ , then counting sort takes  $\Theta(n)$  time.

- But, sorting takes  $\Omega(n \lg n)$  time!
- Where's the fallacy?

## Answer:

- *Comparison sorting* takes  $\Omega(n \lg n)$  time.
- Counting sort is not a *comparison sort*.
- In fact, not a single comparison between elements occurs!

# Stable sorting

Counting sort is a *stable* sort: it preserves the input order among equal elements.

**Exercise:** What other sorts have this property?

# Radix sort

- ***Origin:*** Herman Hollerith's card-sorting machine for the 1890 U.S. Census. (See Appendix )
- Digit-by-digit sort.
- Hollerith's original (bad) idea: sort on most-significant digit first.
- Good idea: Sort on ***least-significant digit first*** with auxiliary ***stable*** sort.

# Operation of radix sort

# Correctness of radix sort

*Induction on digit position*

- Assume that the numbers are sorted by their low-order  $t - 1$  digits.
- Sort on digit  $t$

# Correctness of radix sort

*Induction on digit position*

- Assume that the numbers are sorted by their low-order  $t - 1$  digits.
- Sort on digit  $t$ 
  - Two numbers that differ in digit  $t$  are correctly sorted.

# Correctness of radix sort

*Induction on digit position*

- Assume that the numbers are sorted by their low-order  $t - 1$  digits.
- Sort on digit  $t$ 
  - Two numbers that differ in digit  $t$  are correctly sorted.
  - Two numbers equal in digit  $t$  are put in the same order as the input  $\Rightarrow$  correct order.

# Analysis of radix sort

- Assume counting sort is the auxiliary stable sort.
- Sort  $n$  computer words of  $b$  bits each.
- Each word can be viewed as having  $b/r$  base- $2^r$  digits.

**Example:** 32-bit word

$r = 8 \Rightarrow b/r = 4$  passes of counting sort on base- $2^8$  digits; or  $r = 16 \Rightarrow b/r = 2$  passes of counting sort on base- $2^{16}$  digits.

*How many passes should we make?*

# Analysis (continued)

**Recall:** Counting sort takes  $\Theta(n + k)$  time to sort  $n$  numbers in the range from 0 to  $k - 1$ .

If each  $b$ -bit word is broken into  $r$ -bit pieces, each pass of counting sort takes  $\Theta(n + 2^r)$  time. Since there are  $b/r$  passes, we have

$$T(n, b) = \Theta\left(\frac{b}{r} (n + 2^r)\right).$$

Choose  $r$  to minimize  $T(n, b)$ :

- Increasing  $r$  means fewer passes, but as  $r \gg \lg n$ , the time grows exponentially.

# Choosing $r$

$$T(n, b) = \Theta\left(\frac{b}{r} (n + 2^r)\right)$$

Minimize  $T(n, b)$  by differentiating and setting to 0.

Or, just observe that we don't want  $2^r \gg n$ , and there's no harm asymptotically in choosing  $r$  as large as possible subject to this constraint.

Choosing  $r = \lg n$  implies  $T(n, b) = \Theta(bn/\lg n)$ .

- For numbers in the range from 0 to  $n^d - 1$ , we have  $b = d \lg n \Rightarrow$  radix sort runs in  $\Theta(dn)$  time.

# Conclusions

In practice, radix sort is fast for large inputs, as well as simple to code and maintain.

**Example** (32-bit numbers):

- At most 3 passes when sorting  $\geq 2000$  numbers.
- Merge sort and quicksort do at least  $\lceil \lg 2000 \rceil = 11$  passes.

**Downside:** Unlike quicksort, radix sort displays little locality of reference, and thus a well-tuned quicksort fares better on modern processors, which feature steep memory hierarchies.
